Exam Date

08/14/2008

Patient Name:

Sex: F
DOB: 12/01/1960

Referring Physician:

Examination:

ABDOMEN MRI WITH AND WITHOUT MAGNEVIST

FINAL REPORT

CLINICAL HISTORY:

Elevated gastrin level/Zollinger-Ellison syndrome.

MR IMAGING PROTOCOL:

Multiplanar, multisequence MRI of the abdomen is performed with and without gadolinium enhancement.

MR FINDINGS:

The liver is normal in size, parenchymal signal and enhancement. The gallbladder is surgically absent. There is no dilatation of the intrahepatic bile ducts. The extrahepatic common bile duct is mildly prominent and measures 7.0mm in diameter. The spleen and adrenal glands appear normal. The pancreas is normal in size, parenchymal signal and demonstrates uniform enhancement. The pancreatic duct is not dilated. No cystic mass is demonstrated in the pancreatic bed.

Both kidneys are normal in location and demonstrate symmetric contrast excretion. No enhancing renal mass or perinephric fluid collection is demonstrated. There is no hydronephrosis.

There are no enlarged retroperitoneal lymph nodes or ascites.

Coronal images through the abdomen demonstrate changes of colonic diverticulosis to the descending colon.

Patient Name:

Sex:

F

DOB:

12/01/1960

IMPRESSION:

1. Status-post cholecystectomy with mild prominence to the extrahepatic common bile duct.
2. No MR evidence of enhancing pancreatic mass.
3. Changes of colonic diverticulosis to the descending colon.

Thank you for your referral.
