-----FINAL REPORT -----

CLINICAL HISTORY:

Strong family history of breast CA. History of left breast calcifications at 12 o'clock.

MR IMAGING PROTOCOL:

A series of fat- and water-weighted images in the long- and short-axis views was obtained in conjunction with dynamic contrast-augmented MR with subtraction technique. The contrast was injected via the antecubital fossa at a rate of 3 cc/sec or greater. The patient was imaged at 2-minute or less incremental intervals over a 2½- to 12-minute dynamic period in total. Comparison made with the prior mammogram of 11/20/2007 and 7/13/2006

MR FINDINGS:

Right Breast: Mild to moderate fibroglandular tissue is present, demonstrating mild, gradual enhancement. Small scattered punctate foci of enhancement present, consistent with adenosis.

No evidence of hypervascular invasive or infiltrating mass noted in the right breast. The right nipple, areola and skin are unremarkable. The right chest wall is unremarkable. No evidence of right axillary lymphadenopathy.

Left Breast: Mild to moderate fibroglandular tissue is present, demonstrating mild, gradual enhancement. Small scattered punctate enhancing foci present, consistent with adenosis.

No evidence of hypervascular invasive or infiltrating mass noted in the left breast. The left nipple, areola and skin are unremarkable. The left chest wall is unremarkable. No evidence
